

# CHI-SQUARE TEST ( $\chi^2$ Test)

$\chi^2$  describes the magnitude of discrepancy bet<sup>n</sup> theory and observation.

eg: In tossing of a coin 200 times, the theoretical considerations leads to a result giving head 100 times and tail 100 times but these results are rarely achievable.

If  $O_i$  ( $i=1,2,3,\dots$ ) is a set of observed (experimental) frequencies and  $E_i$  ( $i=1,2,\dots,n$ ) is the corresponding set of expected (theoretical) frequencies.

Then

$$\chi^2 = \sum_{i=1}^n \left[ \frac{(O_i - E_i)^2}{E_i} \right]$$

where  $\sum O_i = \sum E_i = N$

degree of freedom (d.f.) =  $n-1$

Note: ① If  $\chi^2 = 0$  then observed and expected freq. agree exactly.

② If  $\chi^2 > 0$  then they don't agree exactly.

## Degree of Freedom

Degree of Freedom (d.f.),  $\nu = n - k$

where  $n =$  total no. of obs.

$k =$  no. of independent constraints

Q. The following table gives the no. of accidents that took place in an industry various days of the week. Test if accidents are uniformly distributed over the week.

| Day              | M  | T  | W  | Th | F  | S  |
|------------------|----|----|----|----|----|----|
| No. of accidents | 14 | 18 | 12 | 11 | 15 | 14 |

Soln:

Null hypothesis  $H_0$ : The accidents are uniformly distributed over the week.

Under  $H_0$ , the expected freq. of accidents on each

$$\text{day} = \frac{84}{6} = 14$$

|                      |    |    |    |    |    |    |
|----------------------|----|----|----|----|----|----|
| Observed Freq. $O_i$ | 14 | 18 | 12 | 11 | 15 | 14 |
| Expected Freq. $E_i$ | 14 | 14 | 14 | 14 | 14 | 14 |
| $(O_i - E_i)^2$      | 0  | 16 | 4  | 9  | 1  | 0  |

$$\chi^2 = \frac{\sum (O_i - E_i)^2}{E_i}$$

$$= \frac{0 + 16 + 4 + 9 + 1 + 0}{14}$$

$$= \frac{30}{14}$$

$$= 2.1428$$

Significance = 5%

$$n = 6$$

$$\text{d.f.} = n - 1 = 5$$

Conclusion: Table value of  $\chi^2$   
at 5% level of significance  
for  $(6-1=) 5$  d.f is 11.070

∴ Calculated value of  $\chi^2$   
is less than tabulated value

∴  $H_0$  is accepted

i.e. The accidents are uniformly distributed  
over the week.

5% = 0.05  
↑  
level of significance

Row - 5 (d.f)

Col<sup>n</sup> - 0.05

Ans - 11.070

Q. A die is thrown 270 times and  
the results of these throws are given  
below

| No. on the die | 1  | 2  | 3  | 4  | 5  | 6  |
|----------------|----|----|----|----|----|----|
| Frequency      | 40 | 32 | 29 | 59 | 57 | 59 |

Test whether the die is biased or not.

Q. Records taken of the number of male and female births in 800 families having four children are as follows

|                      |    |     |     |     |    |
|----------------------|----|-----|-----|-----|----|
| No. of male births   | 0  | 1   | 2   | 3   | 4  |
| No. of female births | 4  | 3   | 2   | 1   | 0  |
| No. of families      | 32 | 178 | 290 | 236 | 94 |

Test whether the data are consistent with the hypothesis that the binomial law holds and the chance of male birth is equal to that of female namely  $p = q = \frac{1}{2}$

Soln:  $H_0$ : The data are consistent with the hypothesis of equal probability for male and female birth. i.e.  $p = q = \frac{1}{2}$ .

The theoretical frequency is given by

$$N(x) = N \times P(X=x)$$

Here,  $N =$  total freq.

$N(x) =$  no. of families with  $x$  male children

$$P(X=x) = {}^n C_x p^x q^{n-x}$$

where  $p =$  prob. of a male birth

$q =$  " " " female "

$x =$  no. of children

$N(0) =$  No. families with 0 male children

$$= N \times P(X=0)$$

$$= 800 \left[ {}^4 C_0 \left(\frac{1}{2}\right)^0 \left(\frac{1}{2}\right)^4 \right]$$

$$= 800 \times \frac{1}{2^4} = 50$$

$$N(1) = 800 \times P(X=1) = 800 \left[ {}^4C_1 \left(\frac{1}{2}\right)^1 \left(\frac{1}{2}\right)^3 \right]$$
$$= 200$$

$$N(2) = 800 \times P(X=2) = 800 \left[ {}^4C_2 \left(\frac{1}{2}\right)^2 \left(\frac{1}{2}\right)^2 \right]$$
$$= 300$$

$$N(3) = 800 \times P(X=3) = 800 \left[ {}^4C_3 \left(\frac{1}{2}\right)^3 \left(\frac{1}{2}\right) \right]$$
$$= 200$$

$$N(4) = 800 \times P(X=4) = 800 \left[ {}^4C_4 \left(\frac{1}{2}\right)^4 \right]$$
$$= 50$$

|                             |      |      |       |      |       |
|-----------------------------|------|------|-------|------|-------|
| Observed Frequency<br>$O_i$ | 32   | 178  | 290   | 236  | 94    |
| Expected Frequency<br>$E_i$ | 50   | 200  | 300   | 200  | 50    |
| $O_i - E_i$                 | -18  | -22  | -10   | 36   | 44    |
| $(O_i - E_i)^2$             | 324  | 484  | 100   | 1296 | 1936  |
| $\frac{(O_i - E_i)^2}{E_i}$ | 6.48 | 2.42 | 0.333 | 6.48 | 38.72 |

$$\chi^2 = \frac{\sum (O_i - E_i)^2}{E_i} = 54.433$$

Conclusion: Table value of  $\chi^2$  at 5%

level of significance for  $5-1=4$  d.f. is 9.488

$\therefore$  calculated value of  $\chi^2$  is greater than the tabulated value

$\therefore H_0$  is rejected

Hence, the data are not consistent with the hypothesis that the binomial law holds and that the probability of male and female birth is same.

Q. Fit a Poisson distribution to the following data and test the goodness of fit

|     |     |    |    |   |   |
|-----|-----|----|----|---|---|
| $x$ | 0   | 1  | 2  | 3 | 4 |
| $f$ | 109 | 65 | 22 | 3 | 1 |

Note:

① If the data is given in a series of ' $n$ ' numbers then d.f. =  $n-1$

② In case of Binomial dist., d.f. =  $n-1$

③ " " " Poisson dist., d.f. =  $n-2$

④ " " " Normal dist., d.f. =  $n-3$ .
